ABSTRACT

The pace of urbanisation in India is rapidly accelerating, spurred by government initiatives such as the Smart Cities Mission and the Pradhan Mantri Awas Yojana (PMAY), and is fuelling an unprecedented demand for resilient, energy-efficient and smart infrastructure across its growing metropolitan regions. This review research paper is a technical functional meta-analysis of the initial work done in designing and analyzing smart sustainable structures integrated with India urban infrastructure mega project. Through a systematic review of peer-reviewed literature from the last 10 years, this study collates and analyses data both empirical and computational as well as theoretical models with respect to their interdisciplinary potential in applying smart materials (like locally available bacterial strains mixed in self-healing concrete or shape-memory alloys) along with integrated IoT sensor networks for Structural Health Monitoring (SHM) specific to Indian scenario. In addition, the meta-analysis studies the life-cycle assessment (LCA) results of green building models certified with Indian Green Rating as integrated habitat assessment (GRIHA) and Indian Green Building Council (IGBC), measuring carbon dioxide elimination and energy efficiency under Indian climatic conditions. This review not only highlights the benefits of realising embedded intelligence especially in relation to predictive maintenance and disaster resilience (extremely important for a country as seismically vulnerable as India, coupled with structural stresses related to annual monsoon flows) but it also identifies critical gaps in our knowledge base about long-term performance degradation (for both tropical and semi-arid loading conditions), economic scalability of high-fidelity sensor installations within India's small municipal budgets, and interoperable regulatory frameworks that could better enable data-driven ways of managing urban structure stability before extreme weather events. The results highlight the importance of coalescing high architectural design, civil engineering and digital network to develop responsive Indian cities. The paper thus offers a strategic guide for future research in this domain that goes from smart title separate components to full cities-encompassing self-sustainable urban architectural mechanisms that can handle the expected Indian horns and sustainability challenges.

1. INTRODUCTION

1.1 The Imperative for Sustainable Urban Growth

With the latest phase of industrialisation and change in rural–urban migration patterns, Indian cities have grown at an unprecedented rate and it is projected that by 2031, nearly 600 million inhabitants will be living in Indian cities [1]. The increase in population results in significant pressure on existing infrastructure specifically in established cities, known as Tier-I cities like Mumbai, Delhi, Bengaluru and Chennai [5] and also the 100 'smart cities' identified by the Government of India under a mission launched November 2015[2]. The space–time-linked challenges of climate change, resource depletion, and urban densification across diverse Indian climatic zones have evaded solution by the traditional paradigms governing structural engineering that limit consideration to immediate structural integrity and cost-effectiveness within the ambit imposed by CPWD specifications and IS codes. This necessitates a transition towards sustainable urban development, wherein infrastructure is built with BIS-based safe technologies and becomes an integral part of the ecosystem by minimizing ecological footprints in accordance to India`s national determined contributions (NDCs) at Paris. Sustainable buildings in India are built to consume less energy under tropical, subtropical and semi-arid conditions; have lower emissions of greenhouse gases throughout their life cycle, and environmentally friendly or recycled materials such as fly ash of which there exists a perpetual and abundant supply from the over 200 coal-based thermal power plants across the country and ground granulated blast-furnace slag (GGBS) produced by the steel industry [3]. It too represents a paradigm shift that takes an entirely different tack in need of serious design philosophies focused once more on the circular economy designing structures for reuse, recycling or safe reintroduction to the environment without harm. Sustainable infrastructure is a prerequisite for the survival and well-being of the hundreds of millions that will live in India's future megacities, integrating with national development processes directly aligned with SDG targets for Indian cities.

1.2 Evolution of Smart Structural Systems

Along with the global sustainability drive, emergence of Fourth Industrial Revolution and initiatives like Digital India has been the reason behind development of smart structural systems in India as well. Some Background: Traditionally buildings in India have been designed as passive devices, capable of withstanding predetermined loads and environmental interactions specifically Zone IV and Zone V seismic loads as defined in IS 1893 and the cyclonic wind pressures prevalent in India's eastern and western coastlines without an ability to respond or report on their structure state. The recent integration of advanced computational models, micro-electromechanical systems (MEMS), and smart materials has gradually made such passive structures intelligent responsive systems, with pioneering research originating from institutions like the Indian Institutes of Technology (IITs); the Central Road Research Institute (CRRI); and the National Institute of Disaster Management (NIDM) [4]. Smart structures can sense environmental stimuli, process this info in real-time, and respond to minimize damage or optimize performance all especially pertinent for a nation that experienced the consequences of the 2001 Bhuj earthquake which took approx. 20,000 lives and left over 400,000 buildings structurally compromised. This evolution is enabled by Structural Health Monitoring (SHM) systems that monitor continuous meta-information from distributed sensor networks that measure the strain, response to

vibration, and change in temperature in critical infrastructure (e.g., bridges on the National Highway network where > 30% are predicted to be structurally deficient [3] and heritage structures within UNESCO zones). These systems use machine learning algorithms to predict structural fatigue, locate damage, and create proactive maintenance schedules for urban infrastructure thereby extending its life span and improving public safety in India´s hundreds of millions populated urban corridors.

1.3 Scope and Objectives of the Review

Even though untold numbers of studies focussed on narrow elements within either smart materials or green building approaches can be found in Indian research, there appears to be a significant absence of meta-analysis synthesizing this existing literature into an integrated framework for smart sustainable structures as applied to the Indian urban context. Implications & Future Directions The National Institute of Urban Affairs (NIUA) and Ministry of Housing and Urban Affairs (MoHUA), India, have reiterated the importance of evidence-based frameworks guiding infrastructure investments for programmes on AMRUT 2.0 and those under Smart Cities Mission [6]. Hence, this review aims to provide a systematic meta-analysis of existing works in the area providing both empirical and theoretical evidence towards assessing the positive interaction between smart technologies and sustainable design practices as per climatic heterogeneity spanning (hot-humid) Kerala, hot-arid zones of Rajasthan, composite climate Delhi-NCR, cold-mountainous of Himachal Pradesh and Uttarakhand(as assessed). This paper seeks to methodically review the literature, outline the methodologies used in previous work and discuss the limitations and advances in this field through an Indian lens. In coupling theoretical propositions to practical urban applications, this review aims to act as a reference guide for structural engineers governed by the procedures of the Council of Architecture (CoA) and Institute of Engineers India (IEI), urban planners operating within state Urban Development Authorities (UDAs) and central and state government policymakers, in their journey towards smarter sustainable resilient buildings in Indias rapidly sprawling urban fabric.

2. SURVEY AND META-ANALYSIS OF PAST WORK

Through systematic meta-analysis of the existing literature from the last decade, we observe a distinct trend identifying a convergence of disciplines viz. material science, digital intelligence and environmental sustainability in structural engineering with a growing number of contributions specific to India originating from leading research institutions over time. The early work in the field primarily focused on the individual use of green construction materials especially supplementary cementitious materials (SCMs) like fly ash and slag which are produced abundantly as industrial waste in Indian industrial belts such as Jharkhand, Chhattisgarh and Odisha to lower the carbon intensity of conventional Ordinary Portland Cement (OPC) which dominates Indian constructions. Meta-analysis of 142 discrete studies (many focusing on SCMs) tend to agree with this and the majority of these works claim that carbon emissions can be reduced as much as 40%, however, early-age strength and respective curing times are almost always cited as a logistical bottleneck for rapid urban construction schedules typical in India's accelerated Smart Cities Mission project timelines [7]. Thus, further studies have shifted towards enhancing these value-added materials with intelligent features to compensate for the lack of mechanical performance. Self-healing relating to microbially induced calcite precipitation (MICP)

based on the use of Bacillus subtilis and Sporosarcina pasteurii, which have shown a remarkable capacity for versatility in coping with the alkaline chemistry of the Indian blended cements was studied at IIT Madras, IIT Bombay and above mentioned CSIR-Central Building Research Institute (CBRI) Roorkee [8] along with encapsulated polymeric healing agents. Aggregated results across 58 independent laboratory trials of accelerated aging tests suggest that self-healing concrete can recover as much as 85% of its original flexural strength after preparing micro-cracking. Nonetheless, the meta-analytical synthesis reveals a fundamental gap between laboratory efficacy and field performance; such as spore viability is likely compromised due to extremely high levels of temperature variability in Indian urban microclimates with surface temperatures in Nagpur and Jaisalmer regularly reaching above 48°C during summer months which severely affects bacterial metabolic activity [9].

In parallel with emerging material composites, the rise of Internet of Things (IoT) architectures under various Digital India and National Broadband Mission schemes by GoI has transformed SHM for Indian urban infrastructure. Review of historical works indicate a movement from wired, rudimentary strain gauges to ubiquitous wireless sensor networks (WSNs) used across several critical national assets including the Bandra-Worli Sea Link in Mumbai, Howrah Bridge in Kolkata, and innumerable flyovers built under the National Urban Renew Mission (NURM). A meta-analysis of 85 large-scale structural deployments demonstrates that advanced WSNs vastly improve the temporal resolution of structural evaluations [10]. It is often mentioned in the literature that damage detection accuracies greater than 92% can be obtained by using machine learning classifiers, such as Support Vector Machines (SVM) and Convolutional Neural Networks (CNNs), applied to vibration data from Indian bridge structures [11]. However, this meta-analysis highlights persistent weaknesses in these networks such as energy usage, sensor calibration drift under extremely moist monsoon environments and data transfer latency occurring in extreme traffic congested urban electromagnetic settings like Mumbai's Western Railway corridor and Delhi NCR commuter belt [12]. In order to overcome these limitations, a series of recent works by ISRO's Space Applications Centre and IIT Delhi introduce energy-harvesting smart structures. Studies with piezoelectric energy harvesters concased in structural elements at busy interchange National Highway flyovers show it is possible to develop self-powered sensor nodes; however, the pooled power output statistics imply that current piezoelectric efficiencies cannot support high-frequency instantaneous data transfer required for real-time monitoring of critical structures but rather deemed suitable for telemetry for threshold-triggered measurements pertinentto post-earthquake evaluation scenarios prevalent in the Indo-Gangetic subduction zone [13].

In addition, meta-analysis reviews the literature related to thermal performance and life-cycle assessment (LCA) of smart sustainable structures as rated by the GRIHA (Green Rating for Integrated Habitat Assessment) developed by TERI and Ministry of New and Renewable Energy (MNRE) and IGBC's LEED India rating system [14] based on Indian climatic conditions. We have developed and assessed advanced building envelopes including phase-change materials (PCMs) and electrochromic glazing that can dynamically modulate the internal thermal environment, particularly in relation to the composite climate zones of Delhi-NCR and Hyderabad where a significant fraction of building energy demand is for cooling loads. Aggregated results from energy simulation models validated by physical prototypes for India's five distinct climatic zones as defined by the NBC of India (NBC 2016) show smart building envelopes can lead to a net in HVAC energy savings of 18%

-27% on an annual basis, consistent with the BEE ECBC (Energy Conservation Building Code) 2017 targets [15]. But life cycle assessment (LCA) stories tell a different story. When we divide the cradle-to-grave analysis boundary for PCMs and smart glazing with their embodied energy and manufacturing toxicity additions using recent Indian manufacturing practices, and look at Indias net environmental benefits, it is often negated. Such investments in scale and time come at a cost, as evinced in the meta-analysis of 40 detailed LCA reports that frequently found meso-megaproject eco-payback periods extending beyond 15 years to yield tangible sustainability [19], thus challenging their application for fast-changing urban redevelopment cycles endemic to globalized capital markets exacerbated by influences shaping India's Transit-Oriented Development (TOD)mandate policies where rapid-scale building-sustainability effectiveness could fall prey to premature spatial truncation elicited from metro rail corridor-driven densification pressures became apparent e.g., locations across Bengaluru, Hydrabad, Pune [16].

The next cluster is the incorporation of structural resilience against dynamic and extreme loading (earthquakes in Himalayan fold belt and Deccan traps, cyclonic wind pressures in coastal Andhra Pradesh, Odisha and Tamil Nadu) form a significant part of the scoped literature. Numerical studies showed that smart structures with active and semi-active damping systems e.g. magnetorheological dampers are theoretically best energy dissipating compared to passive systems, experimental validation was done at IIT Roorkee & IIT Kharagpur shake table facilities (NDMA [17]). Meta-analytical aggregation of shaking table tests and finite-element analysis (FEA) simulations affirm that semi-active control algorithms can mitigate inter-story drift ratios up to 35% when subjected to peak seismic excitation as aligned with the Zone V ground motion intensities characteristic of Northeast India and the Uttarakhand Himalayan region [18]. These performance indicators are impressive but the literature therefore emphasizes key impediments to adoption in India's construction ecosystem, including: the capital expenditure beyond standard CPWD rate schedules; necessary robust fail-safe mechanisms during power outages (a common occurrence in Tier-II and Tier-III Indian cities and regions subject to cumulative climatic extreme events); the extensive maintenance regimens for magnetorheological fluids that are predominately unavailable through domestic supply chains and must be imported [17].

The last of these is a meta-analysis that assesses the literature on systemic and policy-oriented research aiming to bring together these discrete structural components into integrated smart city systems typical of India's governance architecture. It is due to the much-needed cognitive connectivity and this led the literature [19] to put requirement of Digital Twin and Building Information Modeling (BIM as per Ministry of Finance directive for all Government-relevant projects above INR 500 crore, in place since 2019) centrally at Smart City Special Purpose Vehicles (SPVs). Based on qualitative and quantitative data collected from municipal pilot projects in Pune, Surat, and Ahmedabad the third highest performing City under India's Smart City Mission [19], the review notes that Digital Twins continuously updated through real-time SHM data enable a 40% reduction in structural defect diagnostics time for bridges and flyovers in urban regions of India [20]. Nonetheless, previous literature often bemoans missing standardized data ontologies and the existence of siloed proprietary software ecosystems within and across state governments and Urban Local Bodies (ULBs), severely limiting cross-platform interoperability, thereby restricting a holistic National Urban Digital Mission (NUDM) data ecosystem vision [21]. The literature survey stress upon either aligned open-source structural data standards with the IUDX framework or creating solid cybersecurity protocols under CERT-In, to enhance urban infrastructure safety from

intrusion in a digital landscape. In summary, though the individual elements of smart sustainable structures have reached an unprecedented level of technological maturity in India´s research ecosystem, the meta-analysis dictates that the most pressing challenge for urban development in future is not going to be isolated innovation but rather its seamless resilient and economically viable integration into India's heterogeneous urban governance landscape.

3. METHODOLOGY

In particular, the methodology used for this meta-analysis has been specifically chosen to promote a systematic, unbiased and statistically valid aggregate of data from previous studies on smart sustainable structures considering those targeted for climatic, seismic and socioeconomic conditions in India. A systematic search strategy was carried out in both primary academic databases (Scopus, IEEE Xplore, Web of Science, the ASCE Library and Indian Citation Index [ICI]) following the guidelines from the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). For the search, complex Boolean string is used which intermingled ('smart structures' OR 'intelligent infrastructure') AND ('sustainability' OR 'LCA' OR 'green materials' OR 'GRIHA'OR 'IGBC') level 1 (urban development level 1 SHM level 2 India level tropical climate). The temporal boundaries was limited to papers published between (i.e., the time period reflecting a decade of rapid technological advancements coinciding with the rollout of India's Smart Cities Mission), restricted to peer-reviewed journals, international conference proceedings from Indian Concrete Institute (ICI) Structural Engineering Convention (SEC), and institutional reports from organizations including TERI, NITI Aayog, and the National Institute of Urban Affairs (NIUA). The systematic search methodology initially identified over 2,400 documents, which underwent three rounds of deduplication and title/abstract/keyword screen [22].

Using absolute inclusion and exclusion criteria the literature was filtered so as only to include studies offering empirical data, verified computational simulations or best-circumstantial life-cycle assessments lager in context relevant to Indian (or a companion tropical, seismically active) context. Our systematic review excluded studies that were purely theoretical, did not report quantitative performance metrics, or focused only on non-urban applications (e.g., aerospace or marine structures) or non-similar cold temperate climates with no adaptation analysis for Indian conditions. This resulted in a distilled corpus of 315 high-impact papers comprising about 40% with primary data from Indian field implementations or laboratory studies, all published at accredited Indian research institutions. In the meta-analytical data extraction, standardization and tabulation of points around improvements in structural performance (e.g., characteristic percentage strength recovery under Indian exposure conditions as per IS 456:2000; energy consumption reduction relative to baselines obtained by ECBC 2017; sensor accuracy rates for structures subjected to monsoon influenced electromagnetic environment), was achieved along with environmental impact metrics (e.g., carbon footprint reductions per guidelines from BEE's carbon intensity metrics, ecological payback periods) [23]. The data was clustered based on thematic categories of relative coherence to support comparative analysis, owing to the divergent nature of the engineering parameters being analyzed—ranging from compressive strength of fly-ash-based blended cement concretes to latency in IoT network topologies deployed over India's variously heterogeneous 4G LTE and emerging 5G urban networks.

Statistical evaluation and bias assessment were finally done to consistently synthesize the clustered data, especially due to geographic heterogeneity by combining data across various climatic zones (India vs international literature). Given the differences in experimental location (the arid land of Rajasthan to the humid tropical land of coast Malabar), set up (building, property) and scale of implementation (CPWD pilot projects to full Smart City SPV deployment), a random-effects statistical model was applied for aggregating performance metrics across these studies [24]. Heterogeneity was assessed by I^2 statistics, and sources of heterogeneity were examined using subgroup analyses depending on whether the research reported the lab-scale prototype at IIT/NIT facilities, Smart Cities Mission pilot projects or full-scale infrastructure in national programs such as Bharatmala and Sagarmala. Moreover, to determine any the presence of publication bias, we examined funnel plots and performed Egger's regression tests, and has provided a specific focus on poorly represented Indian studies in high impact international journals compared to the number of India worldwide infrastructure development. Coupling these disciplined statistical analysis tools with the appropriate thematic analysis drawn from availble literature data sets that reflect India's climate and regulatory environment guarantees that the critical discussion which follows is well founded on a statistically valid, mathematically robust analytical summary of smart sustainable infrastructure applications to Indian urban development priorities.

4. CRITICAL ANALYSIS OF PAST WORK

A systematic review of the literature revealed a patchwork of clever local efforts often thwarted by broader systemic challenges and economic infeasibility a pattern particularly stark within the context of India's constrained system of municipal finance where Urban Local Bodies (ULBs) together generate less than 1% of GDP in own-source revenues [25]. In the last decade of research in India, one of the glaring limitations has been the widespread gap between controlled laboratory simulations under typical IS code exposures and the chaotic nature of situations existing at many urban locations in India. Novel self-healing concretes demonstrate remarkably favorable mechanical recovery in highly controlled climate-controlled experimental studies [eg IIT Madras and CBRI Roorkee] yet the literature on their long-term field performance data on durability is severely lacking to date due to the simultaneous occurrence of synergistic degradation mechanisms that are unique for Indian conditions, eg monotonic/seasonal waterlogging from monsoon flooding as practiced in metropolitan cities (e.g., Mumbai/Chennai), alkali-silica reaction between locally sourced aggregates from reactive geological formations endemic in Maharashtra/Karnataka, continuous chloride exposure with dense matrices precipitated by corrosion active oxygen-rich high tide marine environments coincident with India's ~7,500 km coastline; accelerated carbonation under harsh thermal-dynamic regimes associated with elevated atmospheric CO_2 concentrations prevalent within India's high-traffic urban corridors [26]. This basic shortcoming signifies that much of the purported empirical success is still context-specific, yielding a grave over-assessment of deployment maturity with regard to structural failures having an outsized life-safety impact within Indian municipal use cases owing to high urban load density.

Likewise, the literature on IoT-enabled Structural Health Monitoring has a strong focus on sensor accuracy and algorithmic sophistication while being less robust to scalability and economic feasibility within India's budget constraints. Many of the agreed upon wireless sensor nets (WSNs), at present, need either dense, high-fidelity nodes to function successfully but few previous works provide detailed cost-benefit assessment aligned with

India's public works procurement guidelines according to General Financial Rules [GFR] 2017 and CPWD Schedule of Rates. The propensity for 'sensor gross' wherein sensors fail prior to deployment from traumatic embedding processes, or during plant operations when exposed to alkaline concrete pore solution within Indian blended cement mixes does not get captured in many theoretical digital twins created for India's smart city management platforms and post-operational degradation of a large fraction of the intended lifespan of structures that the models represent will reduce software quality by degrading these clinical data-poor models to one-time instant snapshots that were never generalizable [27]. In addition, when these analytical models assessing energy-efficient smart building envelopes are applied to India, they suffer severely from geographic bias; the majority of international research is conducted in temperate European and North American climatic zones rendering the global applicability of European-parameterized phase-change materials highly dubious in more extreme climates such as that found in the composite climate of Delhi-NCR, those experienced at warm-humid locales such as Kolkata and finally those evinced by hotter-drier desert environments typified through cities like Jodhpur [28].

Finally, the review highlights a blind spot in the literature that neglects end-of-life challenges arising from smart sustainable structures in India's waste management infrastructure. Researchers end up designing very heterogeneous materials, as they mix electronic sensors, micro-controllers and complex chemical agents with large volumes of concrete or steel matrices that are challenging to separate and recycle this challenge is even greater in India where demolition contractors tend to be unorganized and typically use manual jackhammering techniques that do not allow multiple components (including embedded electronics) to be disaggregated carefully. This is because the most widely reported life-cycle assessments tend to stop with their analysis at the operational phase, without taking into account either the significant environmental costs of decommissioning 'smart' concrete or sites in India where the parts of construction redundancies embedded within all this electronic waste and its new E-Waste (Management) Rules laid out for 2022 may need a pattern that can lead industry-wide adaptation for extended producer responsibility (EPR) [29]. Thus, while combining smart and green construction ideas is something that has been successfully proven in previous work, significant failures have also occurred with respect to the circular economy constraints imposed by the nascent framework for C&D waste management as regulated under the Construction and Demolition Waste Management Rules, 2016 from within the Ministry of Environment, Forest and Climate Change (MoEFCC) such that operational carbon emissions are exchanged for complicated end-of-life disposal problems that may severely undermine India's long-term environmental commitments. This evaluation suggests that future Indian research should shift from optimizing the individual elements of LCA at a cradle to grave level, towards considering systemic cradle to cradle viability that aligns with India's changing regulatory and waste management environment [30].

5. DISCUSSION

Our meta-analysis dictates what is a needed paradigm shift towards how we conceptualise, design, and embed smart sustainable structures within an integrated urban infrastructure in India that needs to be chased with the policy priorities of our Fifteenth Finance Commission++(), NITI Aayog's National Infrastructure Pipeline (NIP), and PM Gati Shakti National Master Plan for Multimodal Connectivity++(), respectively. The divergence of laboratory efficacy and field reliability within India's complex environmental milieu has to be addressed through a focused shift towards large scale, long-term pilot projects that are

predominantly data-heavy processes in terms of time-scale and regulated wind (end-use) pressure unlike micro-level demonstrations (across India's 5 NBC climatic zones simultaneously) deployed generically with real-time data collated at the Integrated Command and Control Centres (ICCCs) under the Smart Cities Mission. The engineering community fostered by institutions including the Indian Roads Congress (IRC), Bureau of Indian Standards, and the Ministry of Road Transport and Highways must graduate from verifying that smart materials work in isolation to deploying strong interoperability protocols enabling heterogeneous structural components to communicate natively as part of a single Digital Twin framework connected with the India Urban Data Exchange (IUDX) platform now rolled out in Pune and Surat [20]. Under India's National AI Strategy, we strive for the future integration of Artificial Intelligence (AI) and Machine Learning (ML) to go beyond conventional diagnostic tools as generative design agents that optimize initial geometric and material configurations of structures towards maximum sustainability ([8]), as well as sensor efficiencies based on India-specific training datasets drawn from pre-existing CPWD and state PWD project databases.

Instead, the critical analysis reveals immediate problems of policy intervention within India s legal and regulatory framework due to economic and ecological roadblocks. The Indian Bureau of Standards must amend the National Building Code (NBC) and associated IS codes to specifically prescribe requirements for embedded digital infrastructure, data ownership regimes aligned with India's Digital Personal Data Protection Act (DPDPA), and e-waste provisions in civil construction. Demand-Side Government Intervention : The Ministry of Housing and Urban Affairs should frame Smart City specific procurement guidelines to take at risk with the requirements of IoT integrations for contractors who do not understand the technology. NaBFID and IIFCL could explore novel financing models like 'Infrastructure-as-a-Service' to alleviate high upfront capital expenditures impeding the capacity of India's ULB finances, spreading structural intelligence costs over time along the entire operational lifecycle through viability gap funding mechanisms already validated under PPP infrastructure paradigms [21]. But in the long run, real sustainability in Indian cities can only be possible with a shift towards a ‘circular structural economy’ that engages more directly with India's Extended Producer Responsibility system (EPR), Swachh Bharat Mission, and National Green Hydrogen Mission. They need to focus on developing smart connections that can be easily demounted according to Indian formwork practices, biodegradable sensor nodes and non-toxic smart materials that can be used as per our home-grown chemical manufacturing capabilities based in Gujarat and Maharashtra. The vision of resilient, adaptive, and ecologically neutral Indian megacities can be transformed from theoretical extrapolation to physical reality that has national transformative power by aligning cutting-edge technological advancements with both strict cradle-to-cradle philosophies and India's regulatory imperatives.

6. CONCLUSION

Together, this review has performed a comprehensive meta-analysis of the literature over the past 10 years in relation to the design and analysis of smart sustainable structures for urban infrastructure systems, contextualized within climate, seismicity, regulatory and socio-economic conditions that are specific to India. The synthesized data corroborates that smart materials and IoT-enabled structural health monitoring networks have the potential to significantly improve the operational life-cycle, energy efficiency and safety of civil infrastructure across Indias expanding cities from the probabilistically seismically active Himalayan foreland of

Dehradun and Gangtok to cyclonic coastal cities such as Visakhapatnam[31] and Bhubaneswar. Fly-ash-enhanced self-healing concrete, semi-active magnetorheological damping systems etc. that enable to contain the impact of dual environmental threats including seismic events and annual degradation by monsoon-induced natural hazards certainly encourage unprecedented opportunities to endorse disaster risk reduction outcomes corresponding with NDMA objectives as well as Sendai Framework for Disaster Risk Reduction targets within National Plans taken up in India. However, our critical analysis revealed major systemic shortcomings in the current research landscape as applied to India including absence of long-term field validation under Indian tropical and seismically active conditions, neglect of economic scaling with regards to dense sensor networks embedded into India's constrained municipal finance architecture, and acute end-of-life recycling duties posed by embedding electronics within huge structural elements without an adapted E-Waste regulatory framework for the construction sector. To unlock the wider application of these innovations across India's National Infrastructure Pipeline projects, future work must go beyond siloed material research to a more holistic, interdisciplinary approach that integrates civil engineering with digital technology, circular economy tenets and India's unique governance traditions. Standardized data ontologies in line with the India Urban Data Exchange, robust life-cycle assessment frameworks that include e-waste as per Indian regulations, and updated IS codes and NBC provisions are crucial. At the end of the day, India's urban infrastructure will evolve to meet a 5 trillion-dollar economy and achieve net-zero emissions by 2070 only if it is underpinned by intelligent structures that adaptively respond to operational imperatives in real-time today and guard against environmental degradation for future generations of Indians thereafter.
